

Estimates of levels of sex selection abortion in East Asian countries

9 June 2019

Wm. Robert Johnston

Abstract: This report provides estimates of sex selection abortion levels derived from male-female sex ratios at birth for the Republic of Korea, Republic of China (Taiwan), Hong Kong, and PR China. The Republic of Korea, Hong Kong, and PR China all showed a rise in sex select abortions (both estimated numbers and as a fraction of all abortions) when it became possible to determine fetal gender, followed by a decline when sex select abortions were banned. The Republic of China (Taiwan) shows a similar pattern in estimated numbers of sex select abortions, though abortion data is too incomplete to compare to overall abortions.

Introduction

Birth sex ratio statistics allow for estimates of the numbers of abortions for sex selection, although this is complicated by killing or fatal neglect of girls after birth, and by incomplete birth and abortion statistics.

The premise used in these estimates is that abnormal deviations in male-to-female sex ratios at birth (SRB) are due to sex selective abortions. This is generally believed to be the case in the countries examined here, and indeed is affirmed by the response of several of these countries' governments to ban sex select abortions and/or prenatal ultrasounds for the purposes of determining sex. In the case of PR China, high SRB values in the 1980s are more likely to involve other factors such as failure to register female births—with the child being raised illegally, or with the child being killed (infanticide).

Sex select abortions are a profound issue in India, but given the incompleteness of Indian abortion statistics, the high variability of birth sex ratios between states, and the issue of infanticide, India will be evaluated separately in a later report.

Republic of Korea (South Korea)

Data for Republic of Korea in Table 1 is from Johnston (2016a) and sources therein.

Table 1. Data on live births by sex and sex select abortions, Republic of Korea, 1970-2012.

year	live births	sex ratio at birth	male live births	female live births	abortions, interpolated estimates	implied sex select abortions	sex select abortions as % of all abortions

PR China

The PR China government restricts some demographic data, and released data may be incomplete or otherwise suspect. Live births and abortions are from Johnston (2018b) and sources therein. SRB data are from multiple sources: Goodkind and West (2007); Huang et al. (2016); Li (2007); and UNICEF (2015). Two estimates of sex select abortions are provided in Table 4, a low estimate using low SRB values and a natural SRB of 107, and a high estimate using high SRB values and a natural SRB of 106.

Table 4. Data on live births by sex and sex select abortions, PR China, 1982-2015.

Discussion

Figure 1 shows SRB over time for the studied countries, along with SRB for the United States from Mathews and Hamilton (2005). Historically and globally, SRB tends to have a value around 105, corresponding to about 5% more male births than female births. SRB tends to fluctuate over time, particularly for countries with smaller populations due to statistical effects, or for other natural reasons. But this natural variability is low compared to the deviations seen in East Asia in recent decades.

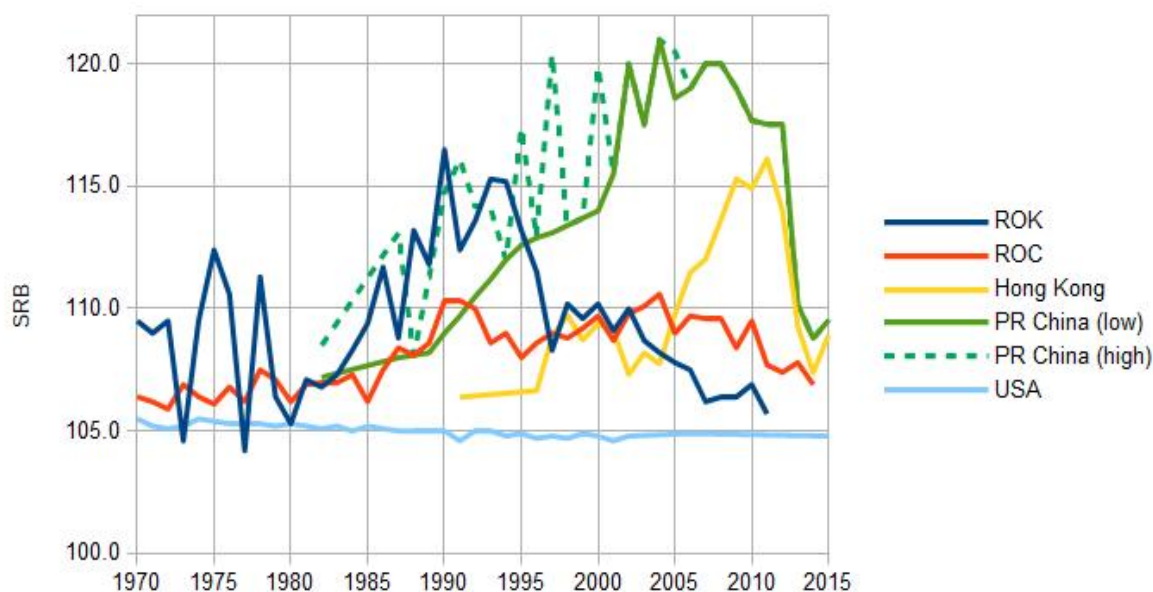

Figure 1. Sex ratio at birth for Rep. of Korea, Rep. of China (Taiwan), Hong Kong, PR China, and the United States.

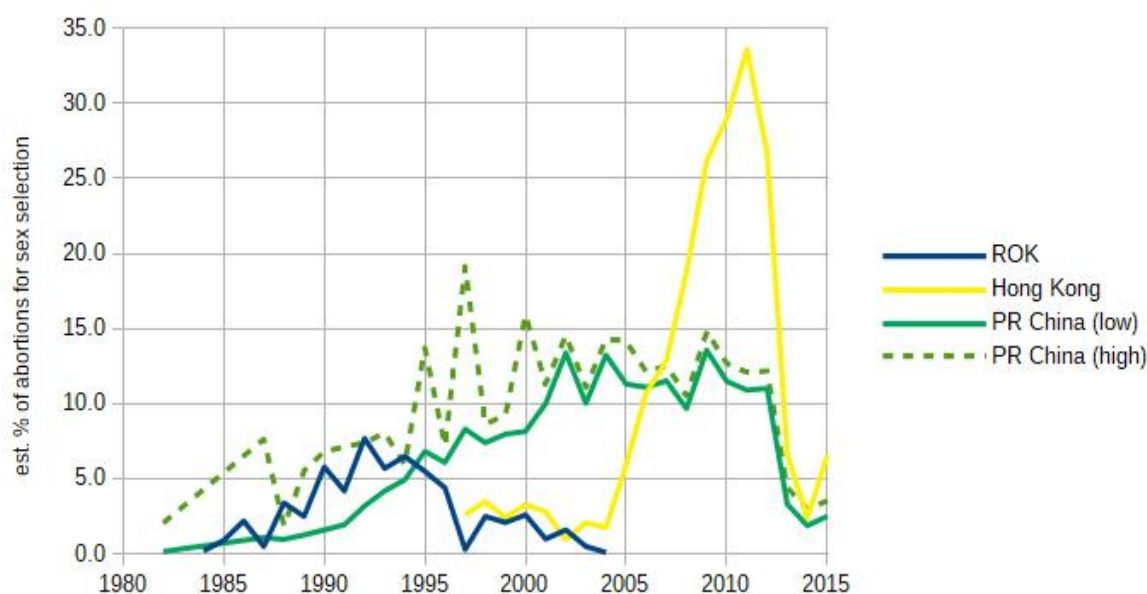

Figure 2. Estimated percentages of abortions for sex selection for Rep. of Korea, Hong Kong, and PR China (high and low estimates).
